Includes tools for calculating mean, median and standard deviation of rows in data frames, detection of outliers, and statistical calculations

Installation

1.1 from PyPI

```
$ python3 -m pip install mathematical --user
```

1.2 from Anaconda

First add the required channels

```
$ conda config --add channels https://conda.anaconda.org/conda-forge
$ conda config --add channels https://conda.anaconda.org/domdfcoding
```

Then install

```
$ conda install mathematical
```

1.3 from GitHub

```
$ python3 -m pip install git+https://github.com/domdfcoding/mathematical@master --user
```

mathematical.data_frames

Mathematical operations for `Data Frames`.

Data:

<code>ColumnLabelList</code>	Type hint for the <code>column_label_list</code> parameter in the <code>df_*</code> functions.
------------------------------	--

Functions:

<code>df_count(row[, column_label_list])</code>	Count the number of occurrences of a non-NaN value in the specified columns of a <code>data frame</code> .
<code>df_data_points(row, column_label_list)</code>	Compile the values for the specified columns in each row into a list.
<code>df_delta(row, left_column, right_column)</code>	Calculate the difference between values in the two columns for each row of a <code>data frame</code> .
<code>df_delta_relative(row, left_column, right_column)</code>	Calculate the relative difference between values in the two columns for each row of a <code>data frame</code> .
<code>df_log(row, column_label_list[, base])</code>	Calculate the logarithm of the values in each row for the specified columns of a <code>data frame</code> .
<code>df_log_stdev(row[, column_label_list])</code>	Calculate the standard deviation of the log10 values in each row for the specified columns of a <code>data frame</code> .
<code>df_mean(row[, column_label_list])</code>	Calculate the mean of each row for the specified columns of a <code>data frame</code> .
<code>df_median(row[, column_label_list])</code>	Calculate the median of each row for the specified columns of a <code>data frame</code> .
<code>df_outliers(row[, column_label_list, ...])</code>	Identify outliers in each row.
<code>df_percentage(row, column_label, total)</code>	Returns the value of the specified column as a percentage of the given total.
<code>df_stdev(row[, column_label_list])</code>	Calculate the standard deviation of each row for the specified columns of a <code>data frame</code> .
<code>set_display_options([desired_width, ...])</code>	Set the display options for numpy and pandas.

ColumnLabelList

Type hint for the `column_label_list` parameter in the `df_*` functions.

Alias of `Optional[Sequence[str]]`

df_count (row, column_label_list=None)

Count the number of occurrences of a non-NaN value in the specified columns of a `data frame`.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Count"] = data_frame.apply(  
    func=df_count,  
    args=[["Bob", "Alice"]],  
    axis=1,  
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label_list** (`Optional[Sequence[str]]`) – List of column labels to count occurrences in. Default `None`.

Return type `int`

Returns Count of the occurrences of non-NaN values.

`df_data_points` (`row, column_label_list`)

Compile the values for the specified columns in each row into a list.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Data Points"] = data_frame.apply(  
    func=df_data_points,  
    args=[["Bob", "Alice"]],  
    axis=1,  
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label_list** (`Sequence[str]`) – List of column labels to calculate standard deviation for.

Return type `List`

Returns The number of data points.

`df_delta` (`row, left_column, right_column`)

Calculate the difference between values in the two columns for each row of a `data frame`.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Delta"] = data_frame.apply(  
    func=df_delta,  
    args=["Bob", "Alice"],  
    axis=1,  
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **left_column** (`str`)
- **right_column** (`str`)

Return type `float`

Returns The difference between `left_column` and `right_column`.

New in version 0.4.0.

`df_delta_relative`(`row, left_column, right_column`)

Calculate the relative difference between values in the two columns for each row of a `data frame`:

```
(left - right) / right
```

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Rel. Delta"] = data_frame.apply(
    func=df_delta_relative,
    args=["Bob", "Alice"],
    axis=1,
)
```

Parameters

- `row`(`Series`) – Row of the data frame.
- `left_column`(`str`)
- `right_column`(`str`)

Return type `float`

Returns The relative difference between `left_column` and `right_column`.

New in version 0.4.0.

`df_log`(`row, column_label_list, base=10`)

Calculate the logarithm of the values in each row for the specified columns of a `data frame`.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Bob Log10"] = data_frame.apply(
    func=df_log,
    args=[[ "Bob"], 10],
    axis=1,
)
```

Parameters

- `row`(`Series`) – Row of the data frame.
- `column_label_list`(`Sequence[str]`) – List of column labels to calculate log for.
- `base`(`float`) – The logarithmic base. Default 10.

Return type `float`

Returns The logarithmic value.

`df_log_stdev`(`row, column_label_list=None`)

Calculate the standard deviation of the log10 values in each row for the specified columns of a `data frame`.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Log_StdDev"] = data_frame.apply(  
    func=df_log_stdev,  
    args=[["Bob", "Alice"]],  
    axis=1,  
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label_list** (`Optional[Sequence[str]]`) – List of column labels to calculate standard deviation for. Default `None`.

Return type `float`

Returns The standard deviation

df_mean (`row, column_label_list=None`)

Calculate the mean of each row for the specified columns of a `data frame`.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Mean"] = data_frame.apply(  
    func=df_mean,  
    args=[["Bob", "Alice"]],  
    axis=1,  
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label_list** (`Optional[Sequence[str]]`) – List of column labels to calculate the mean for. Default `None`.

Return type `float`

Returns The mean

df_median (`row, column_label_list=None`)

Calculate the median of each row for the specified columns of a `data frame`.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Median"] = data_frame.apply(  
    func=df_median,  
    args=[["Bob", "Alice"]],  
    axis=1,  
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label_list** (`Optional[Sequence[str]]`) – List of column labels to calculate median for. Default `None`.

Return type `float`

Returns The median

df_outliers (*row*, *column_label_list=None*, *outlier_mode=1*)

Identify outliers in each row.

This function only returns the list of outliers (if any). If you want the list of values without the outliers see the functions in [mathematical.outliers](#).

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Outliers"] = data_frame.apply(
    func=df_outliers,
    args=[["Bob", "Alice"]],
    axis=1,
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label_list** (`Optional[Sequence[str]]`) – List of column labels to determine outliers for. Default `None`.
- **outlier_mode** (`int`) – outlier detection method to use. Default 1.

The supported outlier modes are:

- 1 or :py:code`mathematical.data_frames.MAD` – Use the Median Absolute Deviation
- 2 or :py:code`mathematical.data_frames.QUARTILES` – Treat values more than $3 \times$ the inter-quartile range away from the upper or lower quartile as outliers.
- 3 or :py:code`mathematical.data_frames.STDEV2` – Treat values more than `rng * stdev` away from mean as outliers

Return type

`List`

Returns The outliers.

df_percentage (*row*, *column_label*, *total*)

Returns the value of the specified column as a percentage of the given total.

The total is usually the sum of the specified column.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Bob Percentage"] = data_frame.apply(
    func=df_percentage,
    args=[13, "Bob"],
    axis=1,
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label** (`str`) – The column to calculate percentage for.
- **total** (`float`) – The total value.

Return type `float`

Returns Percentage * 100

df_stdev(*row, column_label_list=None*)

Calculate the standard deviation of each row for the specified columns of a `data frame`.

Do not call this function directly; use it with `df.apply()` instead:

```
data_frame["Stdev"] = data_frame.apply(  
    func=df_stdev,  
    args=[["Bob", "Alice"]],  
    axis=1,  
)
```

Parameters

- **row** (`Series`) – Row of the data frame.
- **column_label_list** (`Optional[Sequence[str]]`) – List of column labels to calculate standard deviation for. Default `None`.

Return type `float`

Returns The standard deviation

set_display_options(*desired_width=300, max_columns=15, max_rows=20*)

Set the display options for numpy and pandas.

Parameters

- **desired_width** (`int`) – The desired maximum output width, in characters. Default 300.
- **max_columns** (`int`) – The maximum number of columns to display in a `pandas.DataFrame`. Default 15.
- **max_rows** (`int`) – The maximum number of rows to display in a `pandas.DataFrame`. Default 20.

New in version 0.3.0.

mathematical.linear_regression

Functions for performing linear regression.

Data:

<code>ArrayLike_Float</code>	Type hint for arguments that take either a sequence of floats or a numpy array.
------------------------------	---

Functions:

<code>linear_regression_perpendicular(x[, y])</code>	Calculate coefficients of a linear regression $y = a * x + b$.
<code>linear_regression_vertical(x[, y, a, b])</code>	Calculate coefficients of a linear regression $y = a * x + b$.

ArrayLike_Float

Type hint for arguments that take either a sequence of floats or a numpy array.

Alias of `Union[Sequence[float], ndarray]`

linear_regression_perpendicular (x, y=None)

Calculate coefficients of a linear regression $y = a * x + b$. The fit minimizes *perpendicular* distances between the points and the line.

Parameters

- `x` (`Union[Sequence[float], ndarray]`) – 1-D array of floats.
- `y` (`Union[Sequence[float], ndarray, None]`) – 1-D array of floats. Default `None`.

If `y` is omitted, `x` must be a 2-D array of shape $(N, 2)$.

Return type `Tuple[float, float, float, float]`

Returns `(a, b, r, stderr)`, where `a` – slope coefficient, `b` – free term, `r` – Pearson correlation coefficient, `stderr` – standard deviation.

linear_regression_vertical (x, y=None, a=None, b=None)

Calculate coefficients of a linear regression $y = a * x + b$. The fit minimizes *vertical* distances between the points and the line.

Parameters

- `x` (`Union[Sequence[float], ndarray]`) – 1-D array of floats
- `y` (`Union[Sequence[float], ndarray, None]`) – 1-D array of floats. Default `None`.
- `a` (`Optional[float]`) – If specified then the slope coefficient is fixed as this value. Default `None`.

- **b** (`Optional[float]`) – If specified then the free term is fixed as this value. Default `None`.

If y is omitted, x must be a 2-D array of shape $(N, 2)$.

Return type `Tuple[float, float, float, float]`

Returns (a, b, r, stderr) , where a – slope coefficient, b – free term, r – Pearson correlation coefficient, stderr – standard deviation.

mathematical.outliers

Outlier detection functions.

Functions:

<code>mad_outliers(dataset[, strip_zero, threshold])</code>	Identifies outlier values using the Median Absolute Deviation.
<code>quartile_outliers(dataset[, strip_zero])</code>	Identifies outlier values that are more than $3 \times$ the inter-quartile range from the upper or lower quartile.
<code>spss_outliers(dataset[, strip_zero, mode])</code>	Identifies outlier values using the IBM SPSS method.
<code>stdev_outlier(dataset[, strip_zero, rng])</code>	Identifies outlier values that are greater than <code>rng × stdev</code> from mean.
<code>two_stdev(dataset[, strip_zero])</code>	Identifies outlier values that are greater than $2 \times \text{stdev}$ from the mean.

mad_outliers (dataset, strip_zero=True, threshold=3)

Identifies outlier values using the Median Absolute Deviation.

Parameters

- **dataset** (`Sequence`)
- **strip_zero** (`bool`) – Default `True`.
- **threshold** (`int`) – The multiple of MAD above which values are considered to be outliers.
Default 3.

Leys et al. (2013) make the following recommendations:

1. In univariate statistics, the Median Absolute Deviation is the most robust dispersion/scale measure in presence of outliers, and hence we strongly recommend the median plus or minus 2.5 times the MAD method for outlier detection.
2. The threshold should be justified and the justification should clearly state that other concerns than cherry-picking degrees of freedom guided the selection. By default, we suggest a threshold of 2.5 as a reasonable choice.
3. We encourage researchers to report information about outliers, namely: the number of outliers removed and their value (or at least the distance between outliers and the selected threshold)

See also:

https://dipot.ulb.ac.be/dspace/bitstream/2013/139499/1/Leys_MAD_final-libre.pdf

Return type `Tuple[List[float], List[float]]`

Returns A list of the outlier values, and the remaining data points.

quartile_outliers (*dataset*, *strip_zero=True*)

Identifies outlier values that are more than $3 \times$ the inter-quartile range from the upper or lower quartile.

Parameters

- **dataset** (`Sequence`)
- **strip_zero** (`bool`) – Default `True`.

Return type `Tuple[List[float], List[float]]`

Returns A list of the outlier values, and the remaining data points.

spss_outliers (*dataset*, *strip_zero=True*, *mode='all'*)

Identifies outlier values using the IBM SPSS method.

Outlier values are more than $1.5 \times$ IQR from Q1 or Q3.

“Extreme values” are more than $3 \times$ IQR from Q1 or Q3.

Parameters

- **dataset** (`Sequence`)
- **mode** (`str`) – str. Default 'all'.

Return type `Tuple[List[float], List[float], List[float]]`

Returns A list of extreme outliers, a list of other outliers, and the remaining data points.

stdev_outlier (*dataset*, *strip_zero=True*, *rng=2*)

Identifies outlier values that are greater than *rng* \times stdev from mean.

Parameters

- **dataset** (`Sequence`)
- **strip_zero** (`bool`) – Default `True`.
- **rng** (`int`) – Default 2.

Return type `Tuple[List[float], List[float]]`

Returns A list of the outlier values, and the remaining data points.

two_stdev (*dataset*, *strip_zero=True*)

Identifies outlier values that are greater than $2 \times$ stdev from the mean.

Parameters

- **dataset** (`Sequence`)
- **strip_zero** (`bool`) – Default `True`.

Return type `Tuple[List[float], List[float]]`

Returns A list of the outlier values, and the remaining data points.

mathematical.stats

Functions for calculating statistics.

Functions:

<code>absolute_deviation(x[, axis, center, nan_policy])</code>	Compute the absolute deviations from the median of the data along the given axis.
<code>absolute_deviation_from_median(x[, axis, ...])</code>	Compute the absolute deviation from the median of each point in the data along the given axis, given in terms of the MAD.
<code>d_cohen(sample1, sample2[, which, tail, pooled])</code>	Calculates and returns Cohen's effect size index d .
<code>g_durlak_bias(g, n)</code>	Application of Durlak's bias correction to the Hedge's g statistic.
<code>g_hedge(sample1, sample2)</code>	Calculates and returns Hedge's g-Statistic.
<code>interpret_d(d_or_g)</code>	Interpret Cohen's d or Hedge's g values using Table 1 from https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3444174/
<code>iqr_none(dataset)</code>	Calculate the interquartile range, excluding NaN, strings, boolean values, and zeros.
<code>mean_none(dataset)</code>	Calculate the mean, excluding NaN, strings, boolean values, and zeros.
<code>median_absolute_deviation(x[, axis, center, ...])</code>	Compute the median absolute deviation of the data along the given axis.
<code>median_none(dataset)</code>	Calculate the median, excluding NaN, strings, boolean values, and zeros.
<code>percentile_none(dataset, percentage)</code>	Calculate the given percentile, excluding NaN, strings, boolean values, and zeros.
<code>pooled_sd(sample1, sample2[, weighted])</code>	Returns the pooled standard deviation.
<code>std_none(dataset[, ddof])</code>	Calculate the standard deviation, excluding NaN, strings, boolean values, and zeros.
<code>within1min(value1, value2)</code>	Returns whether value2 is within one minute of value1.

absolute_deviation (*x, axis=0, center=<function median>, nan_policy='propagate'*)

Compute the absolute deviations from the median of the data along the given axis.

Parameters

- **x** (`array_like`) – Input array or object that can be converted to an array.
- **axis** (`Optional[int]`) – Axis along which the range is computed. If None, compute the MAD over the entire array. Default 0.
- **center** (`Callable`) – A function that will return the central value. The default is to use `numpy.median`. Any user defined function used will need to have the function signature `func(arr, axis)`. Default <function median at 0x7f3c81e93330>.

- **nan_policy** (`Literal['propagate', 'raise', 'omit']`) – Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default ‘propagate’.

Returns If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `numpy.float64`, then the output data-type is `numpy.float64`. Otherwise, the output data-type is the same as that of the input.

Return type scalar or ndarray

Overloads

- `absolute_deviation(x, axis: None, center = ..., nan_policy = ...) -> float`
- `absolute_deviation(x, axis: int = ..., center = ..., nan_policy = ...) -> ndarray`

Note: The `center` argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=numpy.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

absolute_deviation_from_median (`x, axis=0, center=<function median>, nan_policy='propagate'`)

Compute the absolute deviation from the median of each point in the data along the given axis, given in terms of the MAD.

See also:

<https://eurekastatistics.com/using-the-median-absolute-deviation-to-find-outliers/>

Parameters

- **x** (`array_like`) – Input array or object that can be converted to an array.
- **axis** (`Optional[int]`) – Axis along which the range is computed. If `None`, compute the MAD over the entire array. Default `0`.
- **center** (`Callable`) – A function that will return the central value. The default is to use `numpy.median`. Any user defined function used will need to have the function signature `func(arr, axis)`. Default `<function median at 0x7f3c81e93330>`.
- **nan_policy** (`Literal['propagate', 'raise', 'omit']`) – Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default ‘propagate’.

Returns If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `numpy.float64`, then the output data-type is `numpy.float64`. Otherwise, the output data-type is the same as that of the input.

Return type scalar or ndarray

Overloads

- `absolute_deviation_from_median(x, axis: None, center = ..., nan_policy = ...) -> float`
- `absolute_deviation_from_median(x, axis: int = ..., center = ..., nan_policy = ...) -> ndarray`

Note: The `center` argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=numpy.mean` will calculate the MAD around the mean - it will not calculate the *mean absolute deviation*.

d_cohen(*sample1*, *sample2*, *which*=1, *tail*=1, *pooled*=False)

Calculates and returns Cohen's effect size index **d**.

See also:

Cohen, J. (1988). Statistical power analysis for the behavioral sciences (2nd Edition). Hillsdale, NJ: Lawrence Erlbaum Associates

Parameters

- **sample1** (`Sequence[float]`) – datapoints for first sample
- **sample2** (`Sequence[float]`) – datapoints for second sample
- **which** (`Literal[1, 2]`) – Use the standard deviation of the first sample (1) or the second sample (2). Default 1.
- **tail** (`Literal[1, 2]`) – The number of tails to consider. Default 1.
- **pooled** (`bool`) – Whether to use the pooled standard deviation. Default `False`.

Return type `float`

g_durlak_bias(*g*, *n*)

Application of Durlak's bias correction to the Hedge's g statistic.

n = *n*1+*n*2

Parameters

- **g** (`float`) – Hedge's g-Statistic, calculated using `g_hedge()`.
- **n** (`float`) – The total number of samples in both datasets.

See also:

<https://www.itl.nist.gov/div898/software/dataplot/refman2/auxiliar/hedgeg.htm>

Return type `float`

g_hedge(*sample1*, *sample2*)

Calculates and returns Hedge's g-Statistic.

Formula from <https://www.itl.nist.gov/div898/software/dataplot/refman2/auxiliar/hedgeg.htm>

Parameters

- **sample1** (`Sequence[float]`) – datapoints for first sample
- **sample2** (`Sequence[float]`) – datapoints for second sample

Return type `float`

interpret_d(*d_or_g*)

Interpret Cohen's d or Hedge's g values using Table 1 from <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3444174/>

Parameters `d_or_g` (`float`)

Return type `str`

iqr_none(*dataset*)

Calculate the interquartile range, excluding NaN, strings, boolean values, and zeros.

Parameters `dataset` (`Sequence[Union[float, bool, None]]`) – A list to calculate iqr from.

Return type `float`

Returns The interquartile range.

mean_none(*dataset*)

Calculate the mean, excluding NaN, strings, boolean values, and zeros.

Parameters `dataset` (`Sequence[Union[float, bool, None]]`) – list to calculate mean from

Return type `float`

Returns mean

median_absolute_deviation(*x, axis=0, center=<function median>, scale=1.4826, nan_policy='propagate'*)

Compute the median absolute deviation of the data along the given axis. The median absolute deviation (MAD,¹) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation, but is more robust to outliers². The MAD of an empty array is `numpy.nan`.

Parameters

- `x` (`array_like`) – Input array or object that can be converted to an array.
- `axis` (`Optional[int]`) – Axis along which the range is computed. If None, compute the MAD over the entire array. Default 0.
- `center` (`Callable`) – A function that will return the central value. The default is to use `numpy.median`. Any user defined function used will need to have the function signature `func(arr, axis)`. Default `<function median at 0x7f3c81e93330>`.
- `scale` (`float`) – The scaling factor applied to the MAD. The default scale (1.4826) ensures consistency with the standard deviation for normally distributed data. Default 1.4826.
- `nan_policy` (`Literal['propagate', 'raise', 'omit']`) – Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default ‘propagate’.

Returns If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `numpy.float64`, then the output data-type is `numpy.float64`. Otherwise, the output data-type is the same as that of the input.

Return type scalar or ndarray

Overloads

¹ “Median absolute deviation” https://en.wikipedia.org/wiki/Median_absolute_deviation

² “Robust measures of scale” https://en.wikipedia.org/wiki/Robust_measures_of_scale

- `median_absolute_deviation(x, axis: None, center = ..., scale = ..., nan_policy = ...)`
-> float
- `median_absolute_deviation(x, axis: int = ..., center = ..., scale = ..., nan_policy = ...)`-> ndarray

Note: The `center` argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=numpy.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

References

Examples

When comparing the behavior of `median_absolute_deviation` with `numpy.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> import scipy.stats
>>> import mathematical.stats
>>> x = scipy.stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> mathematical.stats.median_absolute_deviation(x)
1.2280762773108278
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> mathematical.stats.median_absolute_deviation(x)
1.2340335571164334
Axis handling example:
>>> x = numpy.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4], [3, 2, 1]])
>>> mathematical.stats.median_absolute_deviation(x)
array([5.1891, 3.7065, 2.2239])
>>> mathematical.stats.median_absolute_deviation(x, axis=None)
2.9652
```

median_none (dataset)

Calculate the median, excluding NaN, strings, boolean values, and zeros.

Parameters `dataset` (`Sequence[Union[float, bool, None]]`) – list to calculate median from

Return type `float`

Returns standard deviation

percentile_none (dataset, percentage)

Calculate the given percentile, excluding NaN, strings, boolean values, and zeros.

Parameters

- `dataset` (`Sequence[Union[float, bool, None]]`) – Sequence to calculate the percentile from.
- `percentage` (`float`)

Raises `ValueError` if dataset contains fewer than two values

Return type `float`

Returns The interquartile range.

pooled_sd(*sample1*, *sample2*, *weighted=False*)

Returns the pooled standard deviation.

Parameters

- **sample1** (`Sequence[float]`) – datapoints for first sample
- **sample2** (`Sequence[float]`) – datapoints for second sample
- **weighted** (`bool`) – True for weighted pooled SD. Default `False`.

See also:

<https://www.itl.nist.gov/div898/software/dataplot/refman2/auxiliar/hedgeg.htm>

Return type `float`

std_none(*dataset*, *ddof=1*)

Calculate the standard deviation, excluding NaN, strings, boolean values, and zeros.

Parameters

- **dataset** (`Sequence[Union[float, bool, None]]`) – list to calculate mean from.
- **ddof** (`int`) – Means Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where N represents the number of elements. Default 1.

Return type `float`

Returns standard deviation

within1min(*value1*, *value2*)

Returns whether *value2* is within one minute of *value1*.

Parameters

- **value1** (`float`) – A time in minutes.
- **value2** (`float`) – Another time in minutes.

Return type `bool`

mathematical.utils

Utilities for mathematical operations.

Classes:

<code>FRange()</code>	Returns a range of floating-point numbers.
-----------------------	--

Functions:

<code>concatenate_csv(*files[, outfile])</code>	Concatenate multiple CSV files together and return a <code>pandas.DataFrame</code> representing the output.
<code>gcd(a, b)</code>	Returns the GCD (HCF) of <code>a</code> and <code>b</code> using Euclid's Algorithm.
<code>gcd2(numbers)</code>	Returns the GCD (HCF) of a list of numbers using Euclid's Algorithm.
<code>gcd_array(array)</code>	Returns the GCD for an array of numbers using Euclid's Algorithm.
<code>hcf(a, b)</code>	Returns the GCD (HCF) of <code>a</code> and <code>b</code> using Euclid's Algorithm.
<code>hcf2(numbers)</code>	Returns the GCD (HCF) of a list of numbers using Euclid's Algorithm.
<code>intdiv(p, q)</code>	Integer divisions which rounds toward zero.
<code>isint(num)</code>	Checks whether a float is an integer value.
<code>lcm(numbers)</code>	Returns the LCM of a list of numbers using Euclid's Algorithm.
<code>log_factorial(x)</code>	Returns the natural logarithm of <code>x</code> factorial (<code>ln (x !)</code>).
<code>magnitude(x)</code>	Returns the magnitude of the given value.
<code>mod_inverse(a, m)</code>	Returns the modular inverse of <code>a % m</code> , which is the number <code>x</code> such that <code>a * x % m = 1</code> .
<code>nanmean(ls[, dtype])</code>	Returns the mean of the given sequence, ignoring <code>None</code> and <code>numpy.nan</code> values etc.
<code>nanrsd(ls[, dtype])</code>	Returns the relative standard deviation of the given sequence, ignoring <code>None</code> and <code>numpy.nan</code> values etc.
<code>nanstd(ls[, dtype])</code>	Returns the standard deviation of the given sequence, ignoring <code>None</code> and <code>numpy.nan</code> values etc.
<code>remove_zero(inputlist)</code>	Remove zero values from the given list.
<code>represents_int(s)</code>	Checks whether a value can be converted to an <code>int</code> .
<code>roman(num)</code>	Retuns the Roman numeral represtation of the given value.
<code>rounders(val_to_round, round_format)</code>	Round a value to the specified number format, e.g.
<code>strip_booleans(ls)</code>	Remove booleans from a list.
<code>strip_none_bool_string(ls)</code>	Remove <code>None</code> , boolean and string values from a list.
<code>strip_nontype(ls)</code>	Remove <code>None</code> from a list.

continues on next page

Table 2 – continued from previous page

<code>strip_strings(ls)</code>	Remove strings from a list.
--------------------------------	-----------------------------

`class FRange(stop: float)`
`class FRange(start: float, stop: float, step: float = ...)`
Bases: Sequence[float]

Returns a range of floating-point numbers.

The arguments to the range constructor may be integers or floats.

Parameters

- `start` – Default `None`.
- `stop` – Default `None`.
- `step` – Default `1.0`.

Raises `ValueError` – If step is zero, or if any value is larger than 1×10^{14} .

New in version 0.2.0.

Methods:

<code>__contains__(o)</code>	Returns whether <code>o</code> is in the range.
<code>__delattr__(key)</code>	Implement <code>delattr(self, name)</code> .
<code>__eq__(other)</code>	Return <code>self == other</code> .
<code>__getitem__(item)</code>	Returns the value in the range at index <code>item</code> .
<code>__iter__()</code>	Iterates over values in the range.
<code>__len__()</code>	Returns the number of values in the range.
<code>__repr__()</code>	Return a string representation of the <code>FRange</code> .
<code>__reversed__()</code>	Returns <code>reversed(self)</code> .
<code>__setattr__(key, value)</code>	Implement <code>setattr(self, name)</code> .
<code>count(value)</code>	Returns 1 if the value is within the range, 0 otherwise.
<code>index(value)</code>	Returns the index of <code>value</code> in the range.

Attributes:

<code>start</code>	The value of the <code>start</code> parameter (or <code>0.0</code> if the parameter was not supplied)
<code>step</code>	The value of the <code>step</code> parameter (or <code>1.0</code> if the parameter was not supplied)
<code>stop</code>	The value of the <code>stop</code> parameter

`__contains__(o)`
Returns whether `o` is in the range.

Parameters `o` (`object`)

Return type `bool`

`__delattr__(key)`
Implement `delattr(self, name)`.

__eq__(other)
Return `self == other`.

Return type `bool`

__getitem__(item)
Returns the value in the range at index `item`.

Parameters `item`

Overloads

- `__getitem__(i: int) -> int`
- `__getitem__(s: slice) -> FRange`

__iter__()
Iterates over values in the range.

Return type `Iterator[float]`

__len__()
Returns the number of values in the range.

Return type `int`

__repr__()
Return a string representation of the `FRange`.

Return type `str`

__reversed__()
Returns `reversed(self)`.

Return type `Iterator[float]`

__setattr__(key, value)
Implement `setattr(self, name)`.

count(value)
Returns 1 if the value is within the range, 0 otherwise.

Parameters `value (float)`

Return type `int`

index(value)
Returns the index of `value` in the range.

Parameters `value (float)`

Raises `ValueError` – if the value is not in the range.

Return type `int`

start
Type: `float`

The value of the `start` parameter (or `0.0` if the parameter was not supplied)

step

Type: `float`

The value of the `step` parameter (or `1.0` if the parameter was not supplied)

stop

Type: `float`

The value of the `stop` parameter

concatenate_csv (*files, outfile=None)

Concatenate multiple CSV files together and return a `pandas.DataFrame` representing the output.

Parameters

- `*files` (`Union[str, Path, PathLike]`) – The files to concatenate.
- `outfile` (`Union[str, Path, PathLike, None]`) – The file to save the output as. If `None` no file will be saved. Default `None`.

Return type `DataFrame`

Returns A `pandas.DataFrame` containing the concatenated CSV data.

New in version 0.3.0.

gcd(a, b)

Returns the GCD (HCF) of `a` and `b` using Euclid's Algorithm.

Parameters

- `a` (`int`)
- `b` (`int`)

Return type `int`

gcd2(numbers)

Returns the GCD (HCF) of a list of numbers using Euclid's Algorithm.

Parameters `numbers` (`Sequence[int]`)

Return type `int`

gcd_array(array)

Returns the GCD for an array of numbers using Euclid's Algorithm.

Based on <https://www.geeksforgeeks.org/python-program-for-gcd-of-more-than-two-or-array/>

Parameters `array`

Return type `float`

hcf(a, b)

Returns the GCD (HCF) of `a` and `b` using Euclid's Algorithm.

Parameters

- **a** (`int`)
- **b** (`int`)

Return type `int`

hcf2 (*numbers*)

Returns the GCD (HCF) of a list of numbers using Euclid's Algorithm.

Parameters `numbers` (`Sequence[int]`)

Return type `int`

intdiv (*p, q*)

Integer divisions which rounds toward zero.

Examples >>> intdiv(3, 2) 1 >>> intdiv(-3, 2) -1 >>> -3 // 2 -2

Return type `int`

isint (*num*)

Checks whether a float is an integer value.

Note: This function only works with floating-point numbers

Parameters `num` (`float`) – value to check

Return type `bool`

lcm (*numbers*)

Returns the LCM of a list of numbers using Euclid's Algorithm.

Parameters `numbers` (`Sequence[int]`)

Return type `float`

log_factorial (*x*)

Returns the natural logarithm of *x* factorial ($\ln(x!)$).

Parameters `x` (`float`)

Return type `float`

magnitude (*x*)

Returns the magnitude of the given value.

Parameters `x` (`float`) – Numerical value to find the magnitude of.

Changed in version 0.2.0: Now returns the absolute magnitude of negative numbers.

Return type `int`

mod_inverse (*a, m*)

Returns the modular inverse of *a* % *m*, which is the number *x* such that $a \times x \% m = 1$.

Parameters

- **a** (`int`)
- **m** (`int`)

Return type `Optional[float]`

nanmean (`ls, dtype=<class 'float'>`)

Returns the mean of the given sequence, ignoring `None` and `numpy.nan` values etc.

Similar to `numpy.nanmean` except it handles `None`.

Parameters

- **ls** (`Sequence[Any]`)
- **dtype** – Default `float`.

Return type `float`

nanrsd (`ls, dtype=<class 'float'>`)

Returns the relative standard deviation of the given sequence, ignoring `None` and `numpy.nan` values etc.

Parameters

- **ls** (`Sequence[Any]`)
- **dtype** – Default `float`.

Return type `float`

nanstd (`ls, dtype=<class 'float'>`)

Returns the standard deviation of the given sequence, ignoring `None` and `numpy.nan` values etc.

Similar to `numpy.nanstd` except it handles `None`.

Parameters

- **ls** (`Sequence[Any]`)
- **dtype** – Default `float`.

Return type `float`

remove_zero (`inputlist`)

Remove zero values from the given list.

Also removes `False` and `None`.

Parameters `inputlist` (`Sequence[Union[float, bool, None]]`) – list to remove zero values from

Return type `List[float]`

represents_int (`s`)

Checks whether a value can be converted to an `int`.

Parameters `s` (`Any`) – value to check

Return type `bool`

roman (`num`)

Retuns the Roman numeral represtation of the given value.

Examples:

```
>>> roman(4)
'IV'
>>> roman(17)
'XVII'
```

Return type `str`

`rounders` (*val_to_round*, *round_format*)

Round a value to the specified number format, e.g. "0.000" for three decimal places.

Parameters

- **val_to_round** (`Union[str, float, Decimal]`) – The value to round
- **round_format** (`str`) – The rounding format

Return type `Decimal`

`strip_booleans` (*ls*)

Remove booleans from a list.

Parameters `ls` (`Sequence[Any]`) – the list to remove booleans from.

Return type `List`

Returns The list without boolean values.

`strip_none_bool_string` (*ls*)

Remove `None`, boolean and string values from a list.

Parameters `ls` (`Sequence`) – The list to remove values from.

Return type `List`

`strip_nontype` (*ls*)

Remove `None` from a list.

Parameters `ls` (`Sequence[Any]`) – the list to remove `None` from.

Return type `List`

Returns The list without `None` values.

`strip_strings` (*ls*)

Remove strings from a list.

Parameters `ls` (`Sequence[Any]`) – the list to remove strings from.

Return type `List`

Returns The list without strings.

Contributing

mathematical uses `tox` to automate testing and packaging, and `pre-commit` to maintain code quality.

Install `pre-commit` with `pip` and install the git hook:

```
$ python -m pip install pre-commit
$ pre-commit install
```

7.1 Coding style

`formate` is used for code formatting.

It can be run manually via `pre-commit`:

```
$ pre-commit run formate -a
```

Or, to run the complete autoformatting suite:

```
$ pre-commit run -a
```

7.2 Automated tests

Tests are run with `tox` and `pytest`. To run tests for a specific Python version, such as Python 3.6:

```
$ tox -e py36
```

To run tests for all Python versions, simply run:

```
$ tox
```

7.3 Type Annotations

Type annotations are checked using `mypy`. Run `mypy` using `tox`:

```
$ tox -e mypy
```

7.4 Build documentation locally

The documentation is powered by Sphinx. A local copy of the documentation can be built with tox:

```
$ tox -e docs
```

Downloading source code

The mathematical source code is available on GitHub, and can be accessed from the following URL: <https://github.com/domdfcoding/mathematical>

If you have git installed, you can clone the repository with the following command:

```
$ git clone https://github.com/domdfcoding/mathematical
```

```
Cloning into 'mathematical'...
remote: Enumerating objects: 47, done.
remote: Counting objects: 100% (47/47), done.
remote: Compressing objects: 100% (41/41), done.
remote: Total 173 (delta 16), reused 17 (delta 6), pack-reused 126
Receiving objects: 100% (173/173), 126.56 KiB | 678.00 KiB/s, done.
Resolving deltas: 100% (66/66), done.
```

Alternatively, the code can be downloaded in a ‘zip’ file by clicking:

Clone or download → Download Zip

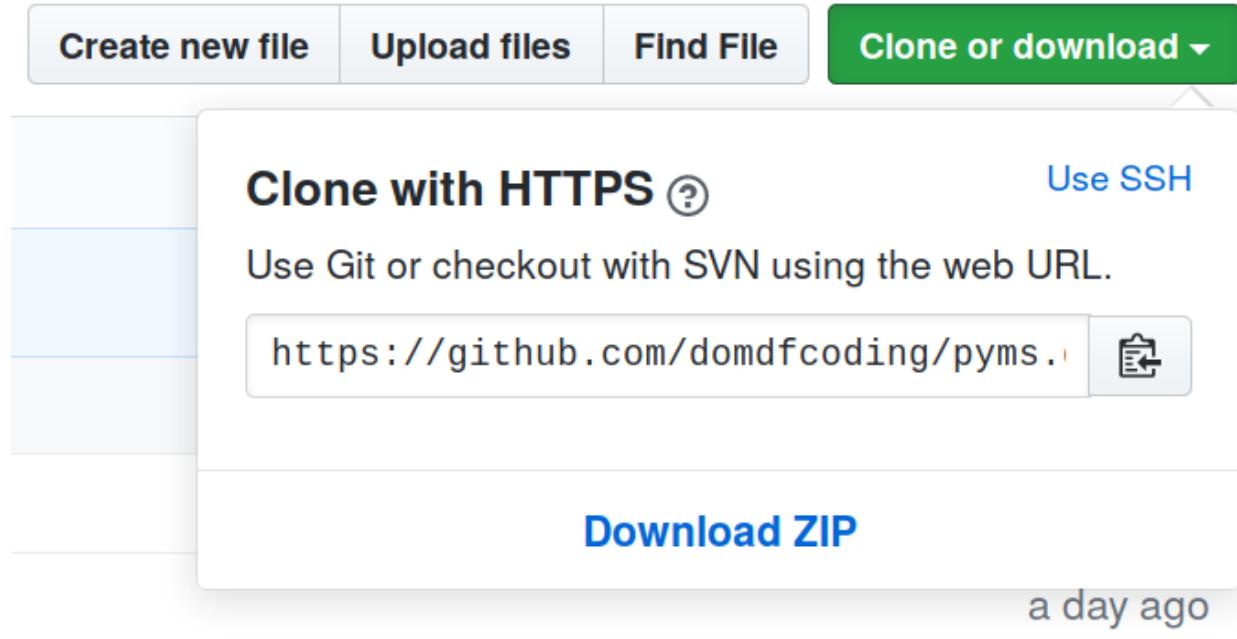

Fig. 1: Downloading a ‘zip’ file of the source code

8.1 Building from source

The recommended way to build `mathematical` is to use `tox`:

```
$ tox -e build
```

The source and wheel distributions will be in the directory `dist`.

If you wish, you may also use `pep517.build` or another [PEP 517](#)-compatible build tool.

License

mathematical is licensed under the [GNU Lesser General Public License v3.0](#)

Permissions of this copyleft license are conditioned on making available complete source code of licensed works and modifications under the same license or the GNU GPLv3. Copyright and license notices must be preserved. Contributors provide an express grant of patent rights. However, a larger work using the licensed work through interfaces provided by the licensed work may be distributed under different terms and without source code for the larger work.

Permissions

- Commercial use – The licensed material and derivatives may be used for commercial purposes.
- Modification – The licensed material may be modified.

GNU LESSER GENERAL PUBLIC LICENSE
Version 3, 29 June 2007

Copyright (C) 2007 Free Software Foundation, Inc. <<https://fsf.org/>>
Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.

(continues on next page)

(continued from previous page)

This version of the GNU Lesser General Public License incorporates the terms and conditions of version 3 of the GNU General Public License, supplemented by the additional permissions listed below.

0. Additional Definitions.

As used herein, "this License" refers to version 3 of the GNU Lesser General Public License, and the "GNU GPL" refers to version 3 of the GNU General Public License.

"The Library" refers to a covered work governed by this License, other than an Application or a Combined Work as defined below.

An "Application" is any work that makes use of an interface provided by the Library, but which is not otherwise based on the Library. Defining a subclass of a class defined by the Library is deemed a mode of using an interface provided by the Library.

A "Combined Work" is a work produced by combining or linking an Application with the Library. The particular version of the Library with which the Combined Work was made is also called the "Linked Version".

The "Minimal Corresponding Source" for a Combined Work means the Corresponding Source for the Combined Work, excluding any source code for portions of the Combined Work that, considered in isolation, are based on the Application, and not on the Linked Version.

The "Corresponding Application Code" for a Combined Work means the object code and/or source code for the Application, including any data and utility programs needed for reproducing the Combined Work from the Application, but excluding the System Libraries of the Combined Work.

1. Exception to Section 3 of the GNU GPL.

You may convey a covered work under sections 3 and 4 of this License without being bound by section 3 of the GNU GPL.

2. Conveying Modified Versions.

If you modify a copy of the Library, and, in your modifications, a facility refers to a function or data to be supplied by an Application that uses the facility (other than as an argument passed when the facility is invoked), then you may convey a copy of the modified version:

- a) under this License, provided that you make a good faith effort to ensure that, in the event an Application does not supply the function or data, the facility still operates, and performs whatever part of its purpose remains meaningful, or
- b) under the GNU GPL, with none of the additional permissions of this License applicable to that copy.

3. Object Code Incorporating Material from Library Header Files.

(continues on next page)

(continued from previous page)

The object code form of an Application may incorporate material from a header file that is part of the Library. You may convey such object code under terms of your choice, provided that, if the incorporated material is not limited to numerical parameters, data structure layouts and accessors, or small macros, inline functions and templates (ten or fewer lines in length), you do both of the following:

- a) Give prominent notice with each copy of the object code that the Library is used in it and that the Library and its use are covered by this License.
- b) Accompany the object code with a copy of the GNU GPL and this license document.

4. Combined Works.

You may convey a Combined Work under terms of your choice that, taken together, effectively do not restrict modification of the portions of the Library contained in the Combined Work and reverse engineering for debugging such modifications, if you also do each of the following:

- a) Give prominent notice with each copy of the Combined Work that the Library is used in it and that the Library and its use are covered by this License.
- b) Accompany the Combined Work with a copy of the GNU GPL and this license document.
- c) For a Combined Work that displays copyright notices during execution, include the copyright notice for the Library among these notices, as well as a reference directing the user to the copies of the GNU GPL and this license document.
- d) Do one of the following:
 - 0) Convey the Minimal Corresponding Source under the terms of this License, and the Corresponding Application Code in a form suitable for, and under terms that permit, the user to recombine or relink the Application with a modified version of the Linked Version to produce a modified Combined Work, in the manner specified by section 6 of the GNU GPL for conveying Corresponding Source.
 - 1) Use a suitable shared library mechanism for linking with the Library. A suitable mechanism is one that (a) uses at run time a copy of the Library already present on the user's computer system, and (b) will operate properly with a modified version of the Library that is interface-compatible with the Linked Version.
 - e) Provide Installation Information, but only if you would otherwise be required to provide such information under section 6 of the GNU GPL, and only to the extent that such information is necessary to install and execute a modified version of the Combined Work produced by recombining or relinking the

(continues on next page)

(continued from previous page)

Application with a modified version of the Linked Version. (If you use option 4d0, the Installation Information must accompany the Minimal Corresponding Source and Corresponding Application Code. If you use option 4d1, you must provide the Installation Information in the manner specified by section 6 of the GNU GPL for conveying Corresponding Source.)

5. Combined Libraries.

You may place library facilities that are a work based on the Library side by side in a single library together with other library facilities that are not Applications and are not covered by this License, and convey such a combined library under terms of your choice, if you do both of the following:

- a) Accompany the combined library with a copy of the same work based on the Library, uncombined with any other library facilities, conveyed under the terms of this License.
- b) Give prominent notice with the combined library that part of it is a work based on the Library, and explaining where to find the accompanying uncombined form of the same work.

6. Revised Versions of the GNU Lesser General Public License.

The Free Software Foundation may publish revised and/or new versions of the GNU Lesser General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Library as you received it specifies that a certain numbered version of the GNU Lesser General Public License "or any later version" applies to it, you have the option of following the terms and conditions either of that published version or of any later version published by the Free Software Foundation. If the Library as you received it does not specify a version number of the GNU Lesser General Public License, you may choose any version of the GNU Lesser General Public License ever published by the Free Software Foundation.

If the Library as you received it specifies that a proxy can decide whether future versions of the GNU Lesser General Public License shall apply, that proxy's public statement of acceptance of any version is permanent authorization for you to choose that version for the Library.
